Using the CCP Module(s)

Author: Mark Palmer

Microchip Technology Inc.

This application note discusses the operation of a Capture/Compare/PWM (CCP) module, and the interaction of multiple CCP modules with the timer resources.

The (CCP) module is software programmable to operate in one of three modes:

- A Capture input
- 2. A Compare output
- 3. A Pulse Width Modulation (PWM) output

For the CCP module to function, Timer resources must be used in conjunction with the CCP module. The desired CCP mode of operation determines which timer resources are required. Table 1 shows the CCP mode with the corresponding timer resource required. Both the Capture and Compare modes require that Timer1 be operating in timer mode or synchronized counter mode.

Note: Capture and Compare modes may not operate if Timer1 is operated in the asynchronous counter mode.

TABLE 1: CCP MODE - TIMER RESOURCE

CCP MODE	Timer Resource	
Capture	Timer1	
Compare	Timer1	
PWM	Timer2	

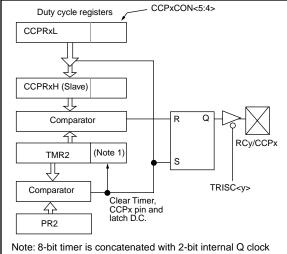

CCP OPERATION

The following three sections discuss the operation of the CCP module in each of its modes of operation. There is a simple example program for each mode of operation. The software example for the Capture mode, also uses a second CCP module in Compare mode to generate the signal to capture.

PWM Mode

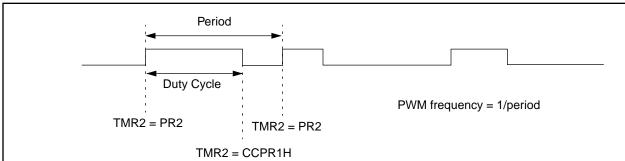

A Pulse Width Modulation output (Figure 1) is a signal that has a time-base (period) and a time that the output stays high (duty cycle). The period is the duration after which the PWM rising edge repeats itself. The resolution of the PWM output is the granularity with which the duty cycle can be varied. The frequency of a PWM is simply the inverse of the period (1/ period).

FIGURE 2: PWM MODE BLOCK DIAGRAM

Note: 8-bit timer is concatenated with 2-bit internal Q clock or 2 bits of the prescaler to create 10-bit time-base.

FIGURE 1: PWM OUTPUT

Each CCP module can support one Pulse Width Modulation (PWM) output signal, with minimal software overhead. This PWM signal can attain a resolution of up to 10-bits, from the 8-bit Timer2 module. This gives 1024 steps of variance from an 8-bit overflow counter. This gives a maximum accuracy of Tosc (50 ns, when the device is operated at 20 MHz). Figure 2 shows a block diagram of the CCP module in PWM mode. When the Timer2 overflows (timer = period register), the value in the duty cycle registers (CCPRxL:CCPRxCON<5:4>) is latched into the 10-bit slave latch. A new duty cycle value can be loaded into the duty cycle register(s) at any time, but is only latched into the slave latch when Timer2 = Timer2 Period Register (PR2).

The period of Timer 2 (and PWM) is determined by the frequency of the device, the Timer2 prescaler value (1, 4 or 16), and the Timer2 Period Register. Equation 1 shows the calculation of the PWM period, duty cycle, and the minimum and maximum frequencies.

Appendix A is a program which generates up to a 10-bit PWM output. The PWM period and duty cycle are updated after the overflow of Timer1. Upon the overflow of Timer1, ports A, B and D are read. The 10-bit duty cycle is specified by the value on PORTB:PORTA<1:0>, while the period is specified by the value on PORTD. By setting the conditional assemble flag PICMaster to TRUE, these values are read from internal registers which are dummy registers for the ports (DUMMY_Px). This allows the software to be verified without the use of hardware and external stimulus.

Since the PWM duty cycle is double buffered, the duty cycle registers are only loaded when there is sufficient time to complete the update of the 10-bit value before the Timer2 = PR2 match occurs. After the duty cycle has been updated and the Timer2 = PR2 match has occurred, the period (stored in the PR2 register) is updated. The operation of the CCP module in PWM mode is similar to the PIC17C42's PWM. Additional concepts of PWM operation can be found in Application Notes AN564 and AN539.

EQUATION 1: PWM PERIOD, DUTY CYCLE, AND FREQUENCIES

PWM Period = [(PR2) + 1] • 4 Tosc • (Timer 2 prescale value)

PWM Duty Cycle = [CCPRxL:CCPRxCON<5:4>] • 4 Tosc • (Timer2 prescale value)

PWM maximum frequency

(High Resolution mode) = 4/(PR2 • TCY)

(Low Resolution mode) = 1/(PR2 • Tcy)

PWM minimum frequency

(High Resolution mode) = 4/(PR2 • Tcy)

(Low Resolution mode) = 1/(PR2 • TCY)

Table 2 shows the minimum and maximum PWM frequency for different device frequencies. The Timer2 prescaler will be selected to give either the minimum or maximum frequencies as shown.

TABLE 2: PWM FREQUENCY FOR DIFFERENT DEVICE FREQUENCIES

20 MHz		ИНz	10 MHz		2 MHz		
PWM Resolution	Min	Max	Min	Max	Min	Max	Units
10-bit	1.22	19.53	0.613	9.77	0.123	1.96	kHz
9-bit	1.22	39.06	0.613	9.77	0.123	3.92	kHz
10-bit	1.22	19.53	0.613	9.77	0.123	1.96	kHz
9-bit	1.22	39.06	0.613	9.77	0.123	3.92	kHz
10-bit	1.22	19.53	0.613	9.77	0.123	1.96	kHz
9-bit	1.22	39.06	0.613	9.77	0.123	3.92	kHz
10-bit	1.22	19.53	0.613	9.77	0.123	1.96	kHz
9-bit	1.22	39.06	0.613	9.77	0.123	3.92	kHz

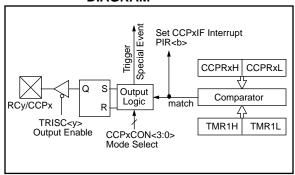

Compare Mode

In Compare mode, the 16-bit value of Timer1 is compared to the CCPRxH:CCPRxL registers. When these registers match, the S/W configured event occurs on the CCPx pin. The events that can be S/W selected are:

- · Clear CCPx pin on match
- · Set CCPx pin on match
- Generate S/W interrupt (CCPx pin unchanged)
- Trigger special event (CCPx pin unchanged)
 - CCP1 clears Timer1
 - CCP2 clears Timer1 and sets the A/D's GO/DONE bit

The CCPxM3:CCPxM0 control bits, in register CCPxCON, configures the operation of the CCP module. The compare function must have the data direction of the CCPx pin configured as an output, if the compare event is to control the state of the CCPx pin.

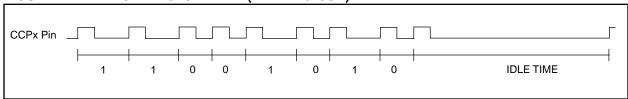

FIGURE 3: COMPARE MODE BLOCK DIAGRAM

When the CCP module is in the OFF state (CCPxM3:CCPxM0 = 0h), the CCPx output latch is forced to a low level, though the level on the CCPx pin will be determined by the value in the data latch of the port. Figure 3 shows the block diagram of the CCP module in Compare mode.

Appendix B is a program which uses the CCP module to transmit a pulse train dependent on the data byte. Timer1 is used as a free running timer, with each "new" compare value being an offset added to the present CCP compare latch value. The data is transmitted every 600 us. Each data bit has a sync pulse (High level) of 8.8 µs. Then the data is transmitted as a low pulse. The time duration of the low pulse determines the value of the data bit. A '0' bit is low for 18.8 us while a '1' bit is low for 37.6 µs. After the last data bit has been transmitted, another sync pulse is transmitted and the output remains low (idle time) until the $600\,\mu s$ data period has completed. An example of the pulse train for the a data byte of 0x0CA is shown in Figure 4. and has an idle time of 224 us. These pulse times are based off the device operational frequency. The program header file, COMP.H, calculates the values to be loaded into the compare registers from the specified Device freq. The data to be transmitted is read from PORTB, during the idle time. By setting the conditional assemble flag PICMaster to TRUE, these values are read from internal registers which are dummy registers for the ports (DUMMY_Px). This allows the software to be verified without the use of hardware and external stimulus.

FIGURE 4: TRANSMIT PULSE TRAIN (DATA = 0x0CA)

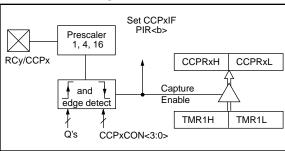

Capture Mode

In Capture mode, the 16-bit value of Timer1 is latched into the CCPRxH:CCPRxL registers, when the S/W configured event occurs on the CCPx pin. The events that can cause a capture are:

- · Every falling edge
- · Every rising edge
- · Every 4th rising edge
- · Every 16th rising edge

The CCPxM3:CCPxM0 control bits, in register CCPxCON, configures the operation of the CCP module. The capture function works regardless of the data direction of the CCPx pin (input or output). With the CCPx pin is configured as an output, a write to the CCPx pin (in PORTC) will cause a capture when the capture requirement is met.

FIGURE 5: CAPTURE MODE BLOCK DIAGRAM

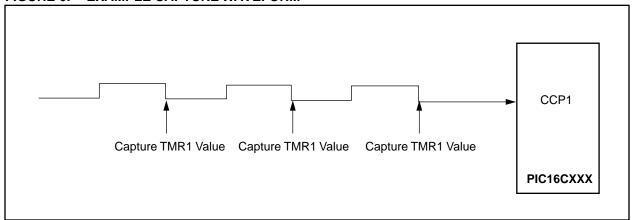

The changing of the Capture mode, via the CCPxM3:CCPxM0 bits, may cause the CCPxIF bit to be set. This "false" interrupt should be cleared (ignored) after changing between capture modes. The CCP prescaler is only cleared by configuring the CCP module into the OFF state (CCPxM3:CCPxM0 = 0h). Figure 5 shows the block diagram of the CCP module in Capture mode. The use of the CCP module in Capture mode is similar to the PIC17C42's capture. Additional concepts of capture operation can be found in Application Note AN545.

Appendix C is a program which implements a 16-bit capture from a free running timer (Timer1). The capture event is configured as each rising edge. The 16-bit capture value is the "new" 16-bit capture value minus the "old" 16-bit capture value. If the time between captures is greater than 2¹⁶ Timer1 increments, an invalid result will occur. This invalid result is not indicated by the software. After the capture period result is calculated, the "new" capture value is loaded into the "old" register.

The waveform that is captured is generated from a second CCP module in compare mode. The value that is loaded in to the CCPR2H:CCPR2L is read from the PORTB and PORTD registers. By setting the conditional assemble flag PICMaster to TRUE, these values are read from internal registers which are dummy registers for the ports (DUMMY_Px). This allows the software to be verified without the use of hardware and external stimulus. Figure 6 shows an input into the CCPx pin, and the capture measurement points.

FIGURE 6: EXAMPLE CAPTURE WAVEFORM

INTERACTION OF CCP MODULES

Due to the modularity of the PIC16CXXX peripherals, future devices with two or more CCP modules on a device are possible. Each CCP module operates independently from the others, though their interaction with the timer resources must be taken into account.

When two or more CCP modules exist on a device, there can be an interaction between the CCP modules. This interaction is shown in Table 3. These interactions do NOT include any interaction (S/W) caused by the main program nor the interrupt service routines of the CCP sources.

Interaction of Two Capture Modes

When two CCP modules are in a Capture mode, Timer1 is the time-base for both captures. This means that they will have the same capture resolution, as determined by the Timer1 prescaler and frequency of the timer/counter clock. This clock can come from an external source (on the RC0/T1OSO/T1CKI pin), but must be synchronized to the device.

Interaction of One Capture Mode and One Compare Mode

When one CCP module is in a Capture mode and a second CCP module is in Compare mode, Timer1 is the time-base for both the captures and the compare. This means that the capture and the compare will have the same resolution, as determined by the Timer1 prescaler and frequency of the timer/counter clock. This clock can come from an external source (on the RC0/T1OSO/T1CKI pin), but must be synchronized to the processor clock. Also, care must be taken in that the compare can be configured to clear TMR1 register (when in special Trigger mode). Care must be taken in system design to ensure that this clearing of the TMR1 register does not have any negative impact on the capture function.

TABLE 3: INTERACTION OF TWO CCP MODULES

CCPx Mode	CCPy Mode	Interaction
Capture	Capture	Same Timer1 time-base.
Capture	Capture	The compare could be configured for trigger special event, which clears the TMR1 register.
Capture	Capture	The compare(s) could be configured for trigger special event, which clears the TMR1 register.
PWM	PWM	The PWMs will have the same frequency, and update rate (Timer2 interrupt).
PWM	Capture	None
PWM	Capture	None

EXAMPLE 1:

<u>ACTION</u>	TIMER1 STATE	COMMENT
CCPR1H:CCPR1L = 0x0465 CCP1CON = 0x?B	0x???? 0x????	CCP1 in Compare - Special Trigger Mode
	0x0232	
CCPR2H:CCPR2L = 0x0165	0x0333	
CCP2CON = 0x?B	0x0334	CCP2 in Compare - Special Trigger Mode
	0x0465	CCP1 resets TMR1 and CCP1 -
:	0x0000	Special Trigger function occurs
	0x0165	CCP2 resets TMR1 and CCP2 -
:	0x0000	Special Trigger function occurs
	0x0165 0x0000	CCP2 resets TMR1 and CCP2 - Special Trigger function occurs

Interaction of Two Compare Modes

When two CCP modules are in a Compare mode, Timer1 is the time-base for both compares. This means that they will have the same compare resolution, as determined by the Timer1 prescaler and frequency of the timer/counter clock. This clock can come from an external source (on the RC0/T1OSO/T1CKI pin), but must be synchronized to the processor clock. Since the compare modules can be configured to clear TMR1 register (when in special Trigger mode), care must be taken in system design to ensure that this clearing of the TMR1 register does not have any negative impact on the compare function. If both compares are configured with a special trigger, which clears the TMR1 register, then the compare register that is closest to (but greater than) the TMR1 register value is the compare value that will reset the TMR1 register. Example 1 shows a possible case.

Interaction of Two PWM Modes

When two CCP modules are in a PWM mode, Timer2 is the time-base for both PWM outputs. This means that they will have the same PWM frequency and update rates, as determined by the Timer2 prescaler and frequency of the device. The resolution of the two PWMs may be different, since each CCP module has its own CCPxX:CCPxY bits for high resolution mode. These bits are found in the CCPxCON<5:4> register.

CONCLUSION

The Capture/Compare/PWM modules offer enormous flexibility in the use of the device timer resources. As with all resources, care must be taken to ensure that no adverse system complications can occur with the interaction between multiple CCP modules. The programs for simple operation of the various CCP modes should be a good foundation for modifications to suite your particular needs.

Note the following details of the code protection feature on PICmicro® MCUs.

- The PICmicro family meets the specifications contained in the Microchip Data Sheet.
- Microchip believes that its family of PICmicro microcontrollers is one of the most secure products of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the PICmicro microcontroller in a manner outside the operating specifications contained in the data sheet. The person doing so may be engaged in theft of intellectual property.
- · Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable".
- Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our product.

If you have any further questions about this matter, please contact the local sales office nearest to you.

Microchip received QS-9000 quality system certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona in July 1999. The Company's quality system processes and procedures are QS-9000 compliant for its PICmicro® 8-bit MCUs, KEELO© code hopping devices, Serial EEPROMs and microperipheral products. In addition, Microchip's quality system for the design and manufacture of development systems is ISO 9001 certified.
